Raw data description

For learning data, mutation profiles of cancer cell lines were obtained from the GDSC, consisting of 21,213 mutation sites, in 1001 cell lines, and the CCLE, providing gene expression mRNA profiles, of 18,988 genes, in 1,037 cell lines. DNA methylation was also obtained from CCLE, including a total of 20,192 positions in promotor regions located 1kb upstream of the transcription start sites of 16,493 genes, in 843 cancer cell lines. Copy number variation from CCLE was obtained, and it includes 17,006 genomic sites, in 1,043 cell lines. PaDEL software (Yap, 2011) generated chemical properties of drugs, from the databases, by taking drug SMILES (simplified molecular-input line-entry system) format as input.

Scenarios of learning dataset construction

For 21,213 mutation sites, mutational events were binarized to either 1 (presence) or 0 (absence), for cancer cell lines. Gene expression profiles (“E”) of the cancer cell lines in the CCLE were standardized through z-normalization.

For DNA methylation (“Y”), the missing values, for each methylation site, was imputed by the ‘impute’ package from Bioconductor (Hastie T, 2019), and, subsequently, DNA methylation values were standardized through Z-normalization. Copy number variation (“O”) data were used as its raw values.

The individual features, in drug chemical property data, were processed using the min-max normalization method. Drug response $\ln(\text{IC}_{50})$ values from the GDSC were used as output values for model learning. The schematic structure of input data is shown in Fig. 2a and Supplementary Figure S1.

ML model construction, according to dataset scenarios

It is noted that, in scenario 1, lasso and ridge were not used, due to extremely slow computation time. Each ML method used the scikit-learn python package. In scenario 1, optimal hyperparameters for SVR, random forest, and XGBoost were selected while searching for the best performance in a set of hyperparameter values (Supplementary Tables S19, S20, and S21). As a result, we selected

0.1 as the regularization parameter C in SVR; 200 as the number of trees in random forest; and 150 and 8 as the number of trees and the depth of trees, respectively, in XGBoost (Supplementary Table S18). In scenarios 2 through 11, ridge and lasso were trained under alpha 0.001; SVR under C 0.01; and random forest and XGBoost under default options (Supplementary Table S18).

Application of the ResNetIC50 model to clinical follow-up observations of chemotherapeutic agents in The Cancer Genome Atlas (TCGA) breast cancer (henceforth, TCGA-BRCA) dataset

From the TCGA-BRCA patients (Cancer Genome Atlas Research Network, 2012), we selected 76 patients under two criteria: (i) patients with at least one mutation; and (ii) patients treated with one out of four chemotherapeutic agents (docetaxel, doxorubicin, gemcitabine, and paclitaxel). In the drug response record of the clinical follow-up data, complete response and stable disease were regarded as responders and clinical progressive disease as non-responders.

In the follow-up, 28 of the 76 patients were treated with docetaxel, with 28 responders and one non-responder. 29 were given doxorubicin, with all responders. One patient was treated by gemcitabine, as a non-responder. 18 were given paclitaxel, all responders.

For predicting $\ln(\text{IC}_{50})$ values, for individual patients, his/her mutation status and drug chemical property vectors of his/her chemotherapeutic administration were concatenated, for input into ResNetIC50. ResNetIC50-predicted $\ln(\text{IC}_{50})$ values were classified under the criterion: $\text{IC}_{50} < 1 \mu\text{M}$ ($\ln(\text{IC}_{50}) < 0$) for responders, and otherwise for non-responders (Lind & Anderson, 2019). We also inspected whether or not the clinical follow-up drug response observations of chemotherapeutic agents were the same with the classified prediction results.

Supplementary Table S1. Description of input datasets in the scenarios. Here, we set various combinations of dataset sizes, genomics data types, and drug information, and we assigned each combination to a dataset name (first column).

Supplementary Figure S2. The architecture of the original CDRScan. Grey boxes represent convolution and fully-connected layers. Cell line genomics vector (e.g., mutation, gene expression, DNA methylation, and copy number variation) and a drug chemical property vector were assigned as the two individual input vectors in the first layer. The original CDRScan only considers a mutation status vector of a cell line in genomics data.

Supplementary Figure S4. The proportion of explainable genomic features overlapped with cancer-context genes over the total number of genomic features. We obtained explainable genomic features by applying LIME to Res-Net models in eleven scenarios. We inspected how many explainable genomic features overlapped with the cancer-context genes in each ResNet model. Subsequently, we calculated the proportion by dividing the number of explainable genomic features overlapped with cancer-context genes by the total number of genomic features. The proportion of explainable genomic features overlapped with the cancer-context genes from (a) the OncoKB (Chakravarty, et al., 2017) and (b) the Cancer Gene Census (CGC) (Sondka, et al., 2018) were represented, respectively. MUT (mutations), EXP (expression), MET (DNA methylation), and CNV (copy number variations).

Supplementary Figure S5. Summary of performance comparisons of the models, in the test sets of all the scenarios, in terms of (a) R^2 , (b) RMSE, and (c) slope. The y-axis represents R^2 , RMSE and slope values, and the x-axis the models. It is noted that lasso and ridge were not available in scenario 1, due to exhaustive computation times. The ResNet trained in scenario 1 is called as ResNetIC50 throughout the manuscript. NA: not available.
